Using the SuperLearner R Package

Eric Polley

Group in Biostatistics University of California, Berkeley

April 2010

Outline

- 1 SuperLearner
- **2** Boston Housing
- 3 ALL data
- 4 van't Veer data

The package is available at:

http://www.stat.berkeley.edu/users/ecpolley/SL/

These slides are available in the package and at:

http://www.stat.berkeley.edu/users/ecpolley/

Need to install R packages **nnls** and **quadprog** before installing **SuperLearner**.

Table: Main functions in the SuperLearner package

Function	Description
SuperLearner CV.SuperLearner listWrappers SuperLearnerNews SL.template screen.template	fits super learner V-fold cross-validated super learner returns list of wrappers in package opens the NEWS file prediction algorithm wrapper template screening algorithm wrapper template

Table: Main arguments for SuperLearner

Name	Description	Req.	Default
Y	outcome	yes	_
X	data.frame for fit	yes	_
newX	data.frame for predict	no	Χ
SL.library	library of algorithms	yes	_
V	number of folds	no	20
shuffle	shuffle rows in X	no	TRUE
verbose	detailed report	no	FALSE
family	error dist.	no	gaussian
method	loss function	no	NNLS

- Y and X are the data used to fit each algorithm (learning data)
- newX is not required but can be a helpful shortcut.
 newX will not be used to fit the models.

Example with X and newX:

```
fit <- glm(Y ~ ., data = X)
out <- predict(fit, newdata = newX)</pre>
```

newX might be a test set, the interesting values of X for prediction, a stacked data.frame with exposure levels set, etc

```
newX

newData <- rbind(
  cbind(A=0, subset(X, select = -A)),
  cbind(A=1, subset(X, select = -A))
)</pre>
```

- family is currently either gaussian() or binomial()
- method can be either "NNLS" or "NNloglik"
- verbose can be helpful to set this to TRUE to see the progress of the estimation.

The ensemble model for "NNLS" is:

$$\Psi_{SL}(W) = \sum_{j=1}^{K} \alpha_j \Psi_j(W), \quad \alpha_j \geq 0, \sum \alpha_j = 1$$

The ensemble model for "NNloglik" is:

$$\Psi_{SL}(W) = \frac{1}{1 + exp\left\{-\sum_{j=1}^{K} \alpha_j \operatorname{logit}_{\gamma}(\Psi_j(W))\right\}}, \quad \alpha_j \ge 0, \sum \alpha_j = 1$$

where $\operatorname{logit}_{\gamma}$ is the trimmed logit function to control when $\Psi_{j}(W)$ is near 0 or 1.

There are two types of algorithms that can be used in SL.library:

- 1 Prediction algorithms. Algorithms that take as input X and Y and return a predicted Y value.
- Screening algorithms. Algorithms designed to reduce the dimension of X. They take as input X and Y and return a logical vector indicating the columns in X passing the screening. Screening algorithms can be coupled with prediction algorithms to form new prediction algorithms.

listWrappers()

Show in R

listWrappers()

There are two ways to specify the algorithms in SL.library:

A character vector:

```
c('SL.glm', 'SL.glmnet', 'SL.gam')
```

2 A list of character vectors:

```
list(c('SL.glm', 'screen.glmP'), 'SL.gam')
```

If only using prediction algorithms, use the first method.

If using screening algorithms, the list is preferred. The syntax for the elements in the list is the prediction algorithm is first, followed by the screening algorithms. Multiple screening algorithms can be used. If a singleton, the default is to apply to all variables.

see the help documents for SuperLearner for more examples of SL.library

Many algorithms are included in the package (use listWrappers() for a list of included functions), but these are not a complete list.

A few reasons to build your own wrappers:

- · Want to use an algorithm not currently included
- Problem suggests different values for the tuning parameters
- Want to select tuning parameters in a different way (e.g. SL.glmnet for selecting λ)
- Need to force variables in model

The **SuperLearner** vignette contains a table of tuning parameters for the algorithms in the package

```
Show in R

vignette("SuperLearner")
```

Example: Creating new prediction algorithm wrapper

Consider the polymars algorithm in the polymars algorithm in the polymars.

- continuous outcome Y
- data.frame of covariates X
- data.frame of covariates newX

```
fit.mars <- polymars(Y, X)
out <- predict.polymars(fit.mars,
    x = as.matrix(newX))</pre>
```

Now we know how to fit the model and return predicted values, next we check out SL.template for integrating the code above into the correct syntax for SuperLearner

Template

```
SL.template <- function(Y.temp, X.temp,
  newX.temp, family, obsWeights, id, ...) {
   if(family$family=="gaussian"){
     # insert estimation function
   }
   if(family$family=="binomial"){
     # insert estimation function
   # out returns predicted responses
   out <- numeric()</pre>
   # fit \leftarrow list(object = )
   fit <- vector("list", length=0)
   foo <- list(out=out, fit=fit)</pre>
   class(foo$fit) <- c("SL.template")</pre>
   return(foo)
```

Table: The arguments passed to a prediction algorithm in SuperLearner

Argument	Description
Y.temp	the outcome variable
X.temp	the training data set
	(the observations used to fit the model)
newX.temp	the validation data set
_	(the observations to return predictions for)
family	a description of the error distribution
id	a cluster identification
obsWeights	observation weights

You do not need to use all these arguments, but if you use any of them, the name must match exactly.

SL.polymars

```
My.SL.polymars <- function(Y.temp, X.temp,
  newX.temp, family, ...) {
  if(family$family=="gaussian"){
    fit.mars <- polymars(Y.temp, X.temp)</pre>
    out <- predict.polymars(fit.mars,
      x = as.matrix(newX.temp))
  if(family$family=="binomial"){
    # insert estimation function
  ... # next slide
```

What about family = binomial()?

Can leave this blank (or add stop('only gaussian')) if only for a specific example with continuous outcome.

To be complete, we could look up the code for a binary outcome and add this case:

```
fit.mars <- polyclass(Y, X, cv = 5)
out <- ppolyclass(cov = newX,
  fit = fit.mars)[, 2]</pre>
```

SL.polymars

```
My.SL.polymars <- function(Y.temp, X.temp,
  newX.temp, family, ...) {
  if(family$family=="gaussian"){
    fit.mars <- polymars(Y.temp, X.temp)</pre>
    out <- predict.polymars(fit.mars,</pre>
      x = as.matrix(newX.temp))
  if(family$family=="binomial"){
    fit.mars <- polyclass(Y.temp, X.temp, cv = 5)</pre>
    out <- ppolyclass(cov = newX.temp,
      fit = fit.mars)[, 2]
  ... # next slide
```

Wrappers need to return 2 values:

- 1 out: predicted Y values for rows in newX
- 2 fit: a list with everything needed to use predict method

In the polymars example: For the gaussian case, predict()
needs: object = fit.mars
For the binomial case, predict() needs: fit = fit.mars

Note: SuperLearner does not use the fit list. If you do not plan to use the function predict. SuperLearner you can leave the fit object as: fit <- vector("list", length = 0)

SL.polymars

```
My.SL.polymars <- function(Y.temp, X.temp,
  newX.temp, family, ...) {
  if(family$family=="gaussian"){
    fit.mars <- polymars(Y.temp, X.temp)</pre>
    out <- predict.polymars(fit.mars,
      x = as.matrix(newX.temp))
    fit <- list(object = fit.mars)</pre>
  if(family$family=="binomial"){
    fit.mars <- polyclass(Y.temp, X.temp, cv = 5)</pre>
    out <- ppolyclass(cov = newX.temp,
      fit = fit.mars)[, 2]
    fit <- list(fit = fit.mars)</pre>
  ... # next slide
```

final step is putting everything together into a list object. The list must have 2 elements and the names must be out and fit

Can also assign a class to the fit element. This will be used to look up the correct predict method. I'm using S3 methods here. This is only important if using predict.SuperLearner afterwards.

See Chambers (2008) *Software for Data Analysis* for details on S3 and S4 methods.

SL.polymars

```
My.SL.polymars <- function(Y.temp, X.temp,
  newX.temp, family, ...) {
  ... # previous slide
  foo <- list(out = out, fit = fit)
  class(foo$fit) <- c("SL.polymars")
  return(foo)
}</pre>
```

Note: foo is just a temporary variable name here.

This should match SL. polymars in the SuperLearner package.

Important notes for creating wrappers

- Input must following naming syntax: Y.temp, X.temp, ...
- Name of new function must be different than one already in the package
- Must return a list with 2 elements named out and fit
- out must be a vector with the predicted Y values for the rows in newX
- fit can be anything if not using predict method, otherwise is a list with elements needed for predict
- A good idea to add ... in the argument

predict.SL.template

```
predict.SL.template <- function (object,
  newdata, family, X = NULL, Y = NULL, ...)
{
  out <- numeric()
  return(out)
}</pre>
```

predict.SL.polymars

```
predict.SL.polymars <-</pre>
function (object, newdata, family, ...) {
  if (family$family == "gaussian") {
    out <- predict.polymars(object = object$object,
      x = as.matrix(newdata))
  if (family$family == "binomial") {
    out <- ppolyclass(cov = newdata,
      fit = object$fit)[, 2]
  return(out)
```

Example: creating screening algorithm

screening template

```
screen.template <- function (Y.temp, X.temp,
   family, obsWeights, id, ...)
{
   if (family$family == "gaussian") {
    }
   if (family$family == "binomial") {
    }
   whichVariable <- rep(TRUE, ncol(X.temp))
   return(whichVariable)
}</pre>
```

Table: The arguments passed to a screening algorithm in SuperLearner

Argument	Description
Y.temp	the outcome variable
X.temp	the training data set
	(the observations used to fit the model)
family	a description of the error distribution
id	a cluster identification
obsWeights	observation weights

You do not need to use all these arguments, but if you use any of them, the name must match exactly.

screen.randomForest

```
screen.randomForest <- function (Y.temp,
 X.temp, family, nVar = 10, ntree = 1000, ...) {
  if (family$family == "gaussian") {
    rank.rf.fit <- randomForest(Y.temp \sim .,
     data = X.temp, ntree = ntree)
  if (family$family == "binomial") {
    rank.rf.fit <- randomForest(
     y = as.factor(Y.temp), x = X.temp,
     ntree = ntree)
  whichVariable <- as.logical(
   rank(-rank.rf.fit$importance) <= nVar)</pre>
  return(whichVariable)
}
```

Boston Housing example

The outcome variable is the median home value (cmedv) for the 506 census tracts of Boston from the 1970 census.

The covariates are a mix of geographical and socioeconomic variables, like per capita crime rate (crim), average number of rooms per house (rm), distance to Boston employment centres (dis), indictor of tract being on the Charles river (chas), etc.

Boston Housing

The Boston Housing data can be found in the **mlbench** package.

Load the data

First need to decide which prediction algorithms to include in the library

Algorithm	Description	Package
glm	linear model	stats
${\tt randomForest}$	random Forest	randomForest
bagging	bootstrap aggregation of trees	ipred
gam	generalized additive models	gam
gbm	gradient boosting	gbm
nnet	neural network	nnet
polymars	polynomial spline regr.	polspline
bart	Bayesian additive regr. trees	BayesTree
glmnet	elastic net	glmnet
svm	support vector machine	e1071
bayesglm	Bayesian glm	arm
step	stepwise glm	stats

One algorithm to consider is the generalized additive model algorithm. This algorithm has a tuning parameter for the degrees of freedom in the smoother. I have set this to be 2 in ${\tt SL.gam}$ but we might want to consider larger values.

We could create an entirely new wrapper for gam and df = 3, or we can write a wrapper for the wrapper and only change the degrees of freedom value.

look at ${\tt SL.gam}$ to see how the degrees of freedom parameter is specified:

SL.gam

```
SL.gam <- function(Y.temp, X.temp, newX.temp,
     family, obsWeights, deg.gam = 2, ...)
  ... # model: Y. temp \sim s(X. temp, deg.qam)
       # see full functions for details
  fit.gam <- gam::gam(gam.model, data = X.temp,
    family = family,
    control = gam.control(maxit = 50, bf.maxit = 50)
    weights = obsWeights)
  out <- predict(fit.gam, newdata = newX.temp,
   type = "response")
  ... # returns list here
}
```

The SL.gam function contains the argument deg.gam = 2.

Wrappers can have additional arguments, but they must have default values.

For the new wrapper, only need to change the value of $\deg.gam$. Use ... to pass everything else between SL.gam.3 and SL.gam.

```
Adjusting df in SL.gam

SL.gam.3 <- function(..., deg.gam = 3) {
    SL.gam(..., deg.gam = deg.gam)
}
```

Easy to create new wrappers by changing tuning parameter values. Check the code for the wrappers by typing the name of the function without parentheses to see what tuning parameter values are in the arguments.

SL.library

```
SL.library <- c("SL.gam",
  "SL.gam.3", "SL.gam.4",
  "SL.gam.5", "SL.gbm.1",
  "SL.gbm.2", "SL.glm",
  "SL.glmnet", "SL.glmnet.alpha25",
  "SL.glmnet.alpha50", "SL.glmnet.alpha75",
  "SL.polymars", "SL.randomForest",
  "SL.ridge", "SL.svm",
  "SL.bayesglm", "SL.step",
  "SL.step.interaction",
  "SL.bart")
```

fitSL

```
fitSL <- SuperLearner(Y = log(DATA$cmedv),
  X = subset(DATA, select = -c(cmedv)),
  V = 10,
  verbose = FALSE,
  SL.library = SL.library,
  shuffle = TRUE,
  family = gaussian()
)</pre>
```

Table: Elements of the output from SuperLearner

Name	Description
SL.predict coef cand.names	super learner predicted values for newX coefficient for each algorithm names of algorithms in library
library.predict	matrix of predicted values for newX from each algorithm in the library
cv.risk	V-fold cross-validated risk for each algorithm in the library

The final super learner prediction model is the weighted combination of the library algorithms where the estimates of the weights can be found with coef(fitSL).

To attain predictions on new observations (not in newX), the predict function will usually work. If you created new wrappers, you also need to create predict S3 methods for those new wrappers.

SuperLearner is a model selection algorithm. It does not contain a good estimate for model assessment (you could use the re-substitution method to estimate the risk but this is optimistic).

Our suggestion to assess the performance of the super learner is to run CV.SuperLearner (example in the next case study).

ALL example

- The outcome variable is an indicator of the molecular biology of the cancer tissue, either Negative or BCR/ABL.
- The sample consists of 79 individuals (42 Neg, 37 BCR/ABL).
- The data contain 2200 features (X) to be used after the filtering steps.
- Need to select algorithms appropriate for a binary outcome and a large number of covariates.

load ALL data

```
# source("http://bioconductor.org/biocLite.R")
# biocLite()
# biocLite("ALL")
library(ALL)
library(genefilter)
data(ALL)
```

The next 2 slides are the processing steps following in Gentleman, Huber and Carey (2008) "Supervised Machine Learning" in *Bioconductor Case Studies*.

```
# restrict to only the NEG and BCR/ABL outcomes
bcell <- grep("^B", as.character(ALL$BT))</pre>
moltyp <- which(as.character(ALL$mol.biol)</pre>
  %in% c("NEG", "BCR/ABL"))
ALL_bcrneg <- ALL[, intersect(bcell, moltyp)]</pre>
#drops unused levels
ALL_bcrneg$mol.biol <- factor(ALL_bcrneg$mol.biol)
# filter features
ALLfilt_bcrneg <- nsFilter(ALL_bcrneg,
  var.cutoff = 0.75)$eset
```

```
# standardize the features
rowIQRs <- function(eSet) {
  numSamp <- ncol(eSet)</pre>
  lowQ <- rowQ(eSet, floor(0.25 * numSamp))</pre>
  upQ <- rowQ(eSet, ceiling(0.75 * numSamp))
  upQ - lowQ
}
standardize <- function(x) {
  (x - rowMedians(x)) / rowIQRs(x)
}
exprs(ALLfilt_bcrneg) <- standardize(
  exprs(ALLfilt_bcrneg))
# convert to numeric matrix for the SuperLearner
Y <- as.numeric(
  ALLfilt_bcrneg$mol.biol == "BCR/ABL")
X <- t(exprs(ALLfilt_bcrneg))</pre>
```

Possible prediction algorithms include:

- · k-nearest neighbors
- elastic net (penalized regression)
- random forest

These algorithms have tuning parameters:

- knn: k
- glmnet: α
- randomForest: mtry and nodesize

randomForest

```
tuneGrid \leftarrow expand.grid(mtry = c(500, 1000, 2200),
  nodesize = c(1, 5, 10)
for(mm in seq(nrow(tuneGrid))) {
   eval(parse(file = "", text =
    paste("SL.randomForest.", mm,
    "<- function(..., mtry = ", tuneGrid[mm, 1],
    ", nodesize = ", tuneGrid[mm, 2], ") {
    SL.randomForest(..., mtry = mtry,
    nodesize = nodesize) }", sep = "")))
```

The code above is hard to follow, but I'm doing the same thing we did with SL.gam. 3 just in a for loop.

```
> SL.randomForest.1
function(..., mtry = 500, nodesize = 1) {
  SL.randomForest(..., mtry = mtry,
 nodesize = nodesize) }
> SL.randomForest.2
function(..., mtry = 1000, nodesize = 1) {
  SL.randomForest(..., mtry = mtry,
 nodesize = nodesize) }
> SL.randomForest.9
function(..., mtry = 2200, nodesize = 10) {
  SL.randomForest(..., mtry = mtry,
 nodesize = nodesize) }
```

SL.library

```
SL.library <- c("SL.knn",
   "SL.knn20",
   "SL.knn30",
   "SL.knn40",
   "SL.knn50",
   "SL.randomForest",
   "SL.glmnet",
   "SL.glmnet.alpha25",
   "SL.glmnet.alpha50",
   "SL.glmnet.alpha75",
   "SL.mean",
   paste("SL.randomForest.",
    seq(nrow(tuneGrid)), sep = ""))
```

ALL example

```
fitSL <- SuperLearner(Y = Y, X = X, V = 10,
   SL.library = SL.library, family = binomial(),
   method = "NNLS", stratifyCV = TRUE)

fitSL</pre>

van't Veer example

- 97 breast cancer patients followed for 5 years.
- Outcome is binary yes/no recur in 5 years (we do not have the date of recurrence)
- 7 clinical variables are available (age, tumor grade, etc.)
- 4348 gene expression values post-filtering

van't Veer data

The original data is available at:

http://www.rii.com/publications/2002/vantveer.html

or send me an email and I can pass along a version for R.

One interesting "screening" is to consider the prediction algorithms on only the clinical variables or on only the gene expression variables.

```
screening
screen.clinical <- function(...){
  return(c(rep(TRUE, 7), rep(FALSE, 4348)))
}
screen.array <- function(...){
  return(c(rep(FALSE, 7), rep(TRUE, 4348)))
}</pre>
```

```
SL.library <- list(</pre>
  c("SL.knn", "All", "screen.clinical",

R packages

Installing suggested packages

```
install.packages(c("glmnet", "randomForest",
  "class", "gam", "gbm", "nnet", "polspline",
  "MASS", "e1071", "stepPlr", "arm", "party",
  "spls", "LogicReg", "nnls", "multicore",
  "SIS", "BayesTree", "quadprog", "ipred",
  "mlbench", "rpart", "caret", "mda", "earth"),
 type="source",
  repos="http://cran.cnr.Berkeley.edu",
  dependencies=c("Depends", "Imports"))
# missing DSA, not available on CRAN
```

Can remove type = 'source' if system not setup to install packages from source.
